

Afterlife of bacterial cell debris: Peptidoglycan in the gastrointestinal tract

Christian Nyffenegger, PhD

Research Scientist, Animal Health and Nutrition

Novozymes A/S, Denmark

novozymes 

Outline

1. The problem: dead bacteria and cell debris in the gut
2. Solving the problem: using a novel microbial muramidase
3. How the solution works

Life after death

Nikolai Fedorovich Gamaleia (1859-1949)

- Worked in Pasteur's lab in 1886
- Later joined Ilya Mechnikov
- studied the effect of injection of dead bacteria in rabbits and sheep

Afterlife of bacterial cell debris

A holistic view of microbiota: includes dead bacteria and cell debris

Live bacteria

+

Dead bacteria
(whole cells + fragments)

Living → Dead → Debris

The problem: dead bacteria and bacterial cell debris in the gut

All parts interact with the host cells in the GIT

Peptidoglycan (PGN): a major component of all bacteria

- PGN dry weight:
 - Gram- 10%
 - Gram+ 80-90%
- Unique biopolymer only found in bacterial cell wall
- Provides structure, shape and counteracts osmotic pressure
- Abundant in the gut

Gram-
bacterium

Gram+
bacterium

Peptidoglycan: a complex polymer forms the bacterial cell wall

Peptidoglycan: a complex polymer forms the bacterial cell wall

Solving the problem

Using a novel microbial muramidase to cleave PGN

A novel microbial muramidase

A novel microbial muramidase

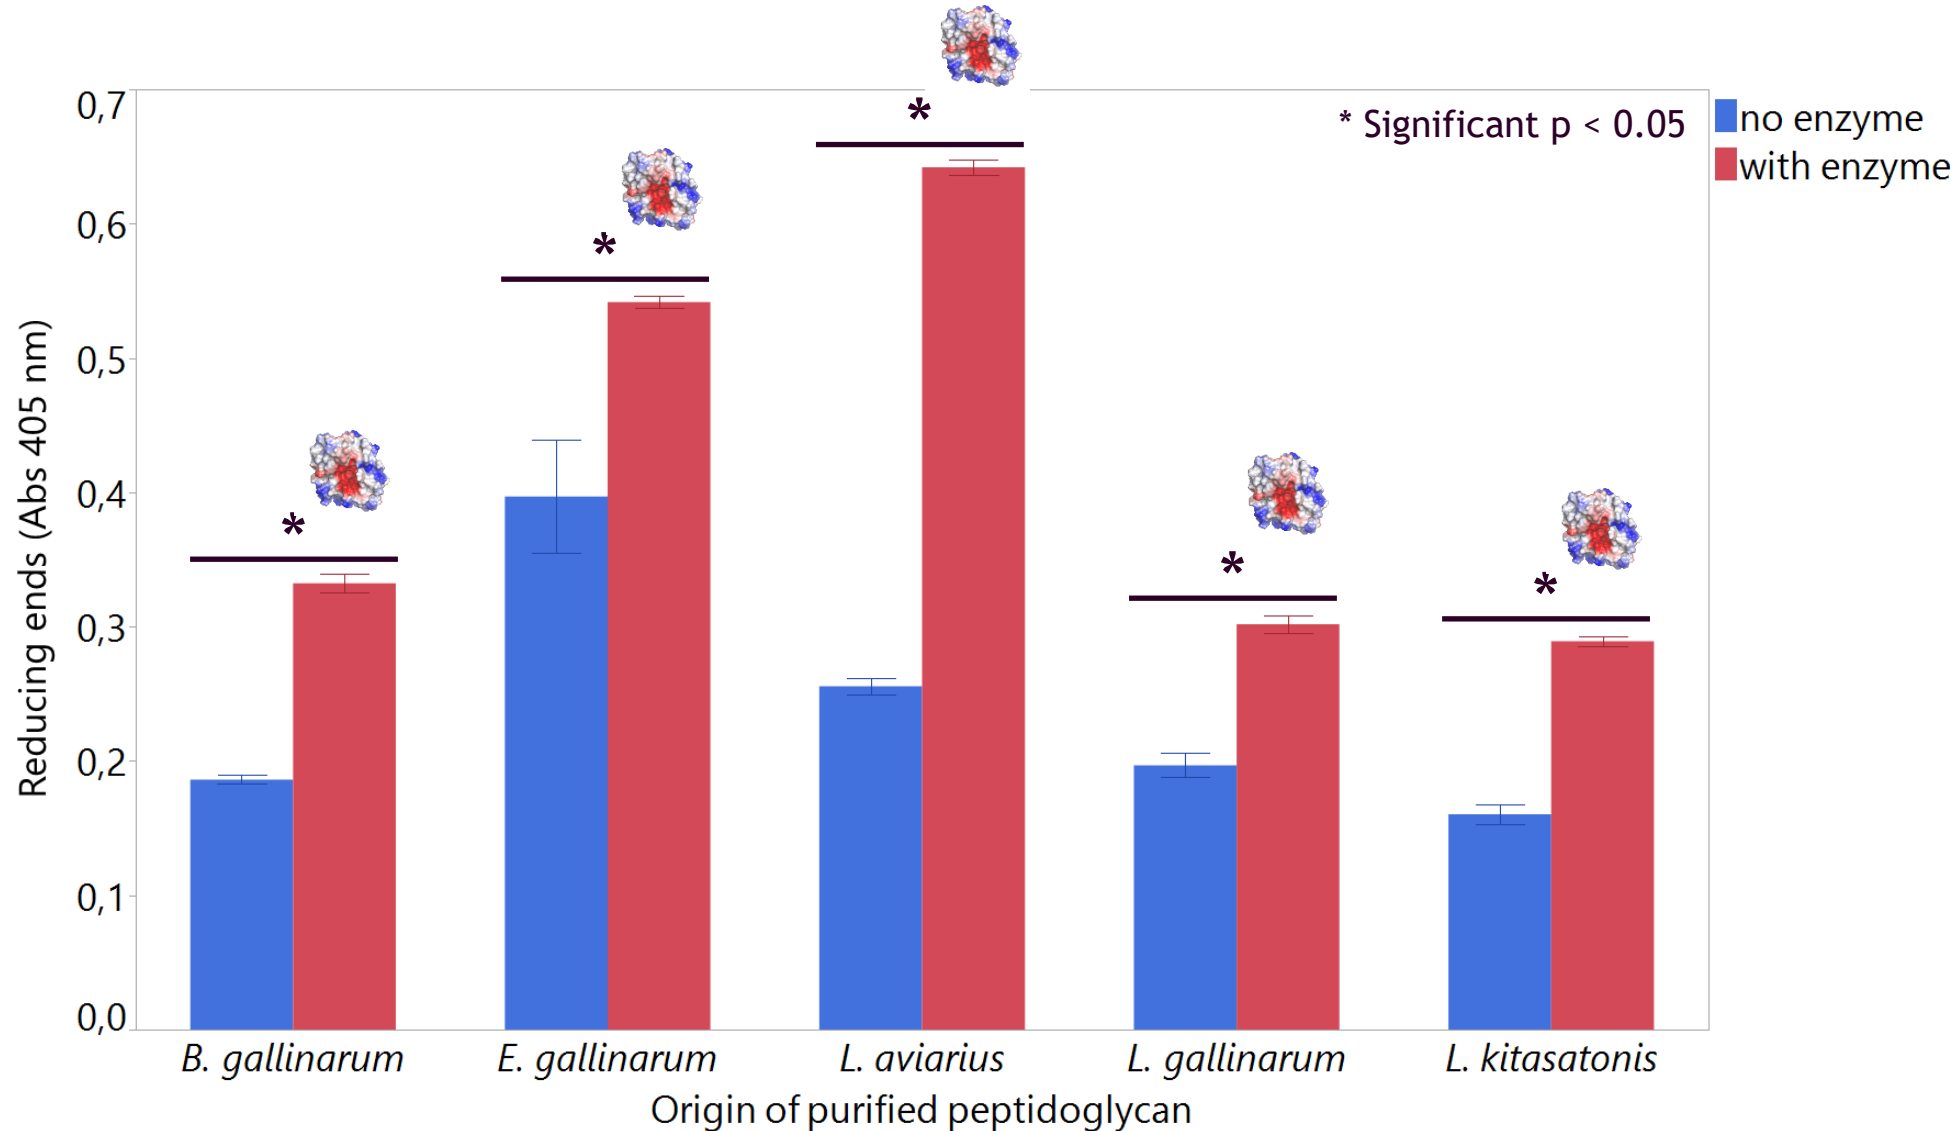

- Hydrolyses peptidoglycan (PGN)
- β -1,4-N-acetylmuramidase activity
- Lack of apparent antimicrobial potency
- The only solution targeting dead and decomposing bacteria

How the solution works

The novel microbial muramidase degrades peptidoglycan from relevant gut bacteria

Microscopy of intact and hydrolyzed peptidoglycan

No enzyme

With enzyme

Enterococcus gallinarum

The novel microbial muramidase depolymerizes peptidoglycan into smaller fragments

Novel microbial muramidase: Impact on animal physiology

In vivo data of a novel microbial muramidase

Safety evaluation of a novel muramidase for feed application

Muramidase supplementation in broiler chicken diet

- Delivers consistent effects in more than 50 *in vivo* studies performed globally.
- Increases body weight gain
- Improved utilization of feed (improved FCR)
- Increased digestibility of key nutrients
- A range of other beneficial effects
- Can save globally 9 million tons of CO2 equivalents.

Effects of the novel microbial muramidase can be measured throughout the GIT

CROP

- Male Cobb 500, 35 days old
- Muramidase dose: 45 000 LSU(F)/kg
- Diet type: Corn-SBM- wheat (15%) + ionophore as coccidiostat

The novel microbial muramidase - first of its kind

- Muramidase enhances gut functionality by cleaning up bacterial debris from GIT
- Muramidase only degrades cell fragments, leaving live bacteria unaffected
- Muramidase catalyzed PGN degradation can be measured in vivo

Thank you

Questions

Further informations about the novel microbial muramidase

Lack of anti-microbial potency confirmed *in vivo* and *in vitro*

In vitro
With 8X dose

No detection of antimicrobial potency in MIC assay

- MIC (Minimal Inhibitory Concentration) assay is the industry-standard measurement of antimicrobial potency
- 7 reference strains recommended by the European Food Safety Authority
- 30 field strains isolated from poultry

In vivo
With 10X dose

No significant reduction in caecal bacterial counts

- Total caecal aerobes and anaerobes (CFU/g)
- Enterobacteria, Coliforms, Lactobacilli (CFU/g)

Conformational selection: “Smart” muramidase distinguishes between peptidoglycan conformations

Live cells

Stretched due to pressure inside live cell
(Turgor pressure: up to 20 atm)

Dead cells

Relaxed due to lack of pressure from live cell

Monomer quantification

**Chemical hydrolysis to
single muramic acid sugars**

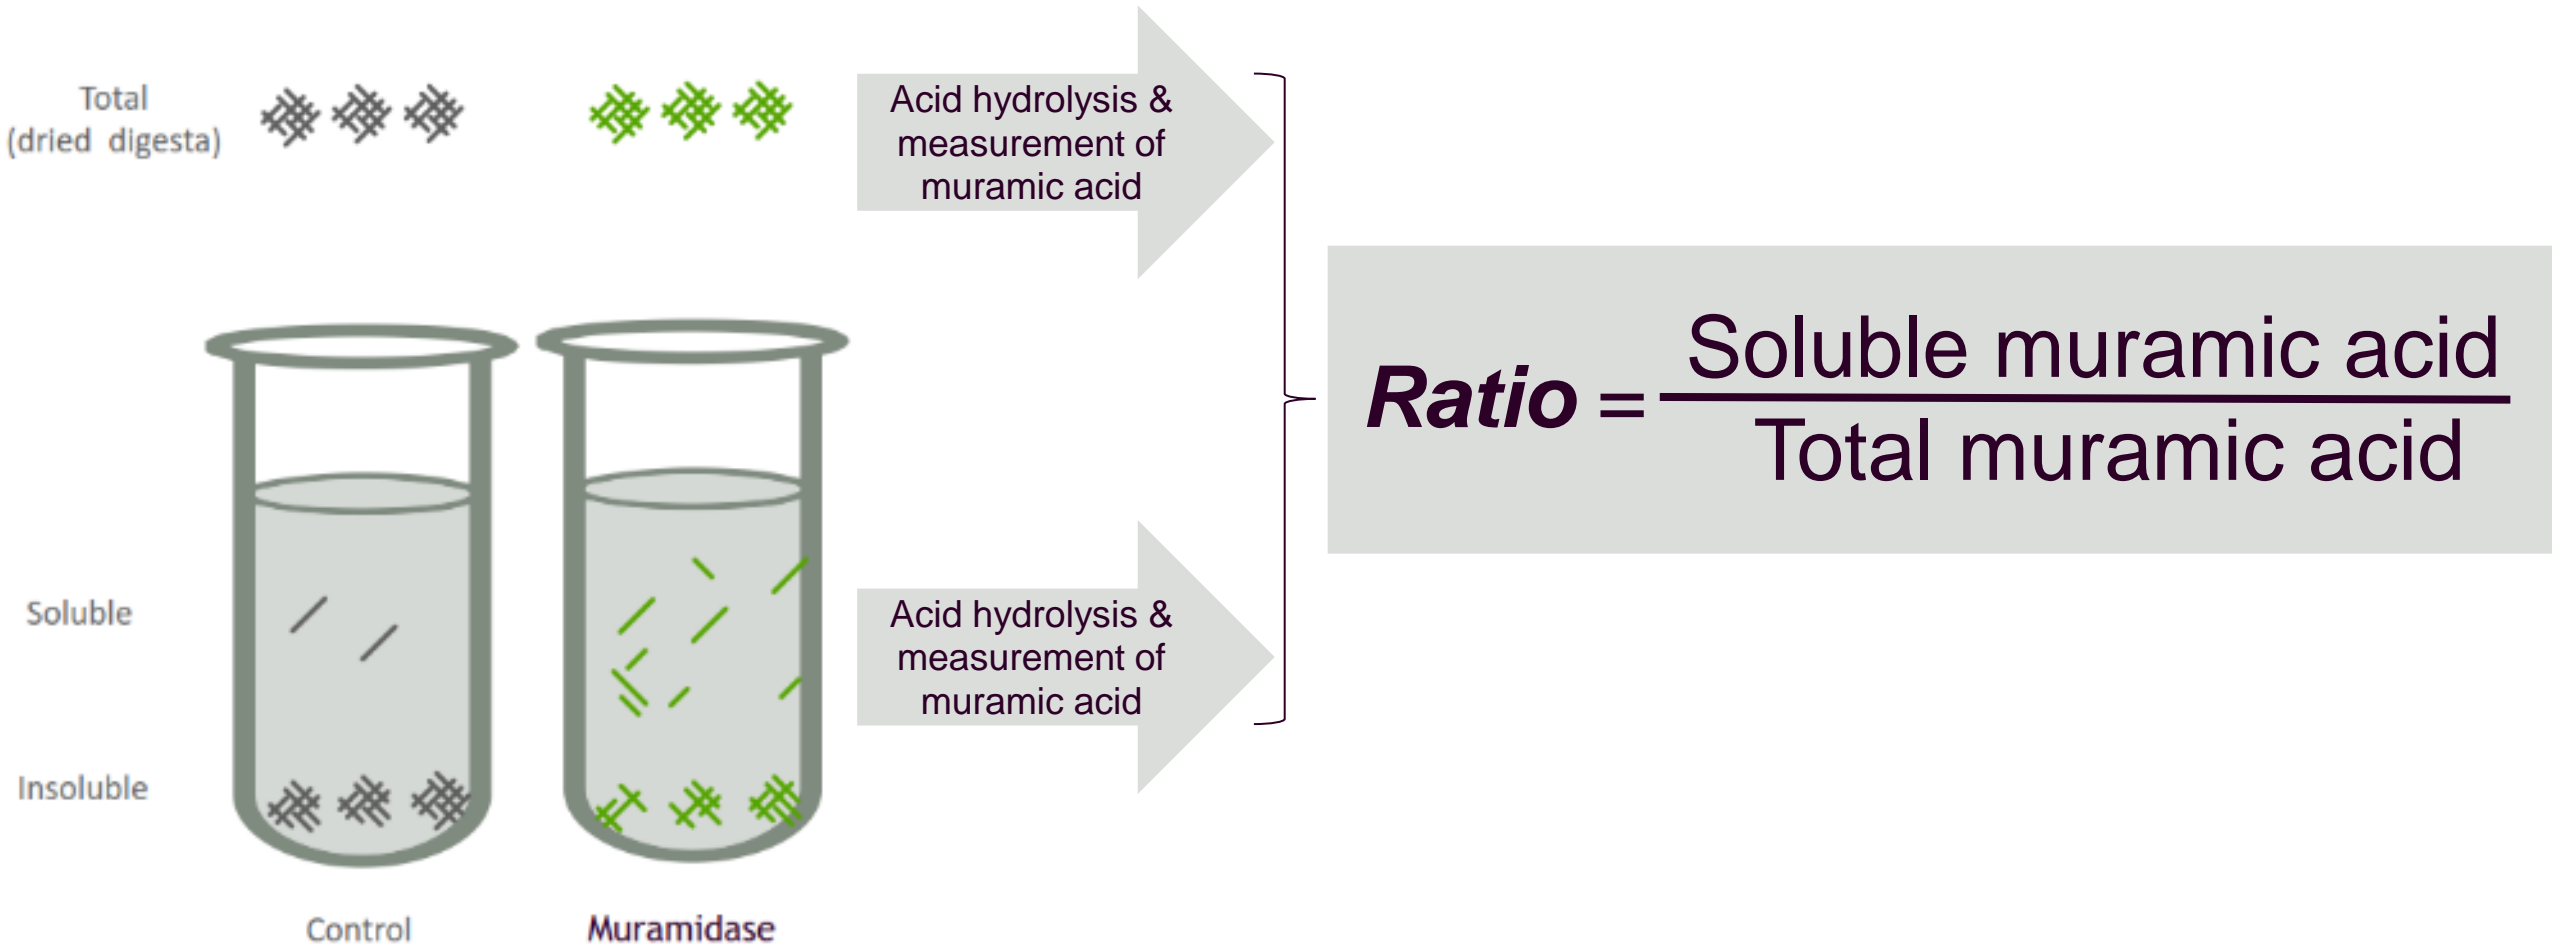

5 M hydrochloric acid (pH<0)
for 24 hours at 100°C

Quantification of muramic acid

Novel method to quantify PGN degradation in digesta samples through muramic acid analysis

Muramidase

vs

hen egg white lysozyme

Chicken type lysozyme =antimicrobial

Hen egg white lysozyme and other higher animals

GH22

C-like lysozyme (c for chicken)

Hydrolysis of 1→4 beta linkage

Found in milk, saliva, mucus, tears, egg-white

First enzyme, structure was solved in 1960ies

Classical Koshland retaining mechanism containing covalent glycosyl intermediate

Side activity on chitin (also 1→4 beta linkage)

Glu35=cat residue, Asp52 catalytic nucleophile in large cleft

127 aa, 4 disulphide bonds, 5 helical regions (40% of aa), five regions of beta sheet with rc and beta turns

Structure shard with GH19 (chitinases), GH23(lysozymes (goose)), GH124 (cellulases), GH134 (mannanases)

~130 aa

Novel microbial mura- Midase =not antimicrobial

Fungal muramidase

GH25

“Chalaropsis”-like lysozyme

Hydrolysis of 1→4 beta linkage

β-1,4-N-acetylmuramidase activities

Likely retaining

Mechanism=neighboring group participation

Structure unrelated to GH22 etc.

TIM-barrel (eight-stranded beta barrel flanked by 6 (normally 8) alpha helices

Long groove in C-terminal face, culminating in deep whole of highly neg electrostatic potential = cat site

DIE motif (D and E cat residues, around pos 100)

~200 aa

Mechanism

Retaining mechanism for a β -glycosidase:

HEWL-koshland mechanism

Novel microbial muramidase: neighbouring group participation
